Question 1: Describe the structure and function of the mitochondria.
Answer: The mitochondria are double-membraned organelles found in most eukaryotic cells. They are often referred to as the "powerhouses" of the cell because they generate most of the cell's adenosine triphosphate (ATP) through a process called cellular respiration. The outer membrane is smooth and serves as a barrier, while the inner membrane is folded into structures called cristae, increasing surface area for metabolic reactions. Let's delve into some sample questions and their comprehensive answers.

Sample Questions and Answers from Section 9 Biology Workbook

Question 1: Explain the concept of an ecosystem and describe its main components.

Answer: An ecosystem is a community of living organisms interacting with each other and with their non-living environment within a specific area. The main components of an ecosystem include:

- Biotic Factors:** All living organisms such as plants, animals, bacteria, fungi, and other microorganisms.
- Abiotic Factors:** Non-living physical and chemical elements like sunlight, water, temperature, soil, and nutrients.

These components are interconnected, with biotic factors relying on abiotic factors for survival, and biotic interactions influencing the environment. Ecosystem functioning depends on the balance and health of these components.

Question 2: Describe the flow of energy in an ecosystem and explain why it is considered unidirectional.

Answer: Energy flow in an ecosystem begins with sunlight, which is captured by autotrophs (like green plants) through photosynthesis. This energy is then transferred through the food chain via consumers and decomposers. The process follows these steps:

- Producers:** Convert solar energy into chemical energy (glucose).
- Primary Consumers:** Herbivores that feed on plants.
- Secondary and Tertiary Consumers:** Carnivores and omnivores that eat other animals.
- Decomposers:** Break down dead organic matter, returning nutrients to the soil.

The energy flow is considered unidirectional because energy is lost at each trophic level primarily as heat due to metabolic processes, and only a fraction (usually around 10%) is transferred to the next level. This makes energy flow linear and non-recyclable within the ecosystem.

Question 3: What are biodiversity hotspots, and why are they important for conservation?

Answer: Biodiversity hotspots are regions that are rich in endemic species (species found nowhere else) but are also severely threatened by human activities. To

qualify as a hotspot, a region must meet two criteria: It must contain at least 1,500 endemic vascular plant species. It must have lost at least 70% of its original natural vegetation. Examples include the Amazon Rainforest, Madagascar, and the Western Ghats. These areas are critical for conservation because they harbor a significant proportion of the planet's biodiversity. Protecting hotspots helps preserve unique species and maintains ecological balance and resilience.

Question 4: How does deforestation impact the carbon cycle and global climate?

Answer: Deforestation has a profound impact on the carbon cycle and contributes to global climate change in several ways:

- Reduced Carbon Sequestration:** Trees absorb CO₂ during photosynthesis. Deforestation decreases the number of trees available to absorb CO₂, leading to higher atmospheric CO₂ levels.
- Release of Stored Carbon:** When trees are cut and burned or decay, stored carbon is released back into the atmosphere as CO₂.
- Altered Local Climate:** Loss of forests affects local humidity and temperature regulation, further influencing climate patterns.

Overall, deforestation accelerates climate change by increasing greenhouse gases and disrupting natural carbon sinks.
